Introduction to Association Rule Mining – Market Basket Analysis (MBA)

Association rule mining is a data mining technique used to uncover **if-then relationships** between items in large datasets, such as retail transaction logs. These relationships, known as **association rules**, capture patterns of items that frequently occur together (called **co-occurrences**).

In the context of **market basket analysis**, association rules help answer questions like: *"Which products are often bought together?"* For example, suppose we find that 75% of customers who buy cereal also buy milk. We can express this as the rule:

$$\{\text{cereal}\} \Rightarrow \{\text{milk}\}$$

This rule suggests that customers who purchase cereal often purchase milk as well. Such insights can guide **marketing and retail decisions**, including promotional strategies, product bundling, and shelf placement.

Association Rule Use Cases and Domains

#	Domain	Use Case	Description (what + why it's useful)	Example Association / Pattern
1	Healthcare	Disease diagnosis	Identifying associations between symptoms and diseases to support faster, more accurate diagnosis	{fever, cough} → {flu}
2	Healthcare	Drug interactions	Discovering meds often prescribed together or risky combos to improve treatment safety	{drug A, drug B} → {adverse reaction}
3	Web Usage Mining	Website optimization	Analyzing navigation paths to remove friction and increase conversions	{homepage, product page} → {checkout}
4	Web Usage Mining	Recommendation systems	Finding frequently co-accessed content to power “you may also like” recommendations	{clicked “smartphone”} → {clicked “smartphone accessories”}
5	Education	Student behavior analysis	Finding patterns in course enrollment to improve course offerings and planning	{math101, cs101} → {stat101}
6	Education	Learning paths	Identifying typical learning sequences to design better curricula and study plans	{topic A, topic B} → {topic C}
7	Telecommunications	Customer churn analysis	Detecting usage patterns linked to cancellations to target retention campaigns	{low data usage, few calls} → {churn}
8	Telecommunications	Service bundling	Finding services often bought together to create attractive bundles and offers	{broadband, mobile} → {TV subscription}
9	Banking & Finance	Fraud detection	Uncovering transaction patterns linked to fraud to trigger alerts and investigations	{high transaction frequency, odd hours} → {fraud}
10	Banking & Finance	Loan approvals	Identifying traits of successful loans to refine credit policies and scoring models	{high income, good credit score} → {loan approved}

#	Domain	Use Case	Description (what + why it's useful)	Example Association / Pattern
11	Manufacturing	Fault detection	Linking machine conditions to failures for early warning and preventive maintenance	{high temperature, low pressure} → {equipment failure}
12	Manufacturing	Supply chain optimization	Discovering material usage patterns to optimize inventory and production planning	{material A, material B} → {product C}
13	Retail (beyond basket)	Shelf placement	Grouping products often bought together to improve store layout and increase sales	{item A, item B} → {co-located on shelf}
14	Retail (beyond basket)	Customer segmentation	Finding purchase behavior patterns to tailor promotions to specific customer segments	{frequent discount purchases} → {low brand loyalty}
15	Social Media Analysis	Trending topics	Finding hashtag co-occurrences to understand themes and plan relevant content	{#climatechange, #sustainability} → {#renewableenergy}
16	Social Media Analysis	User behavior patterns	Analyzing engagement sequences to optimize content for likes, comments, and shares	{likes post, comments on post} → {shares post}
17	Energy Sector	Usage patterns	Linking context (time, devices) to consumption peaks to improve demand forecasting	{high A/C usage, weekend} → {peak energy consumption}
18	Energy Sector	Smart grid analysis	Detecting conditions before failures to improve grid reliability and maintenance	{low voltage, high demand} → {power outage}
19	Transportation & Logistics	Traffic analysis	Discovering conditions that cause congestion to improve planning and routing	{morning rush hour, bad weather} → {traffic jam}
20	Transportation & Logistics	Route optimization	Finding route combinations tied to faster delivery to optimize logistics operations	{route A, route B} → {delivered faster}
21	E-commerce	User preferences	Identifying viewing/buying	{view item A} → {view similar item B}

#	Domain	Use Case	Description (what + why it's useful)	Example Association / Pattern
22	E-commerce	Cross-selling	patterns to personalize recommendations and UX	
23	Sports Analytics	Performance metrics	Finding items frequently bought together to suggest add-ons and increase basket value	{bought laptop} → {bought laptop bag}
24	Sports Analytics	Injury prevention	Linking player actions to outcomes to guide tactics and training	{high possession, accurate passes} → {win}
			Identifying conditions before injuries to adjust training load and reduce risk	{high training load, lack of rest} → {injury risk}

Approaches to Association Rule Mining

To discover meaningful patterns such as items frequently bought together, we need methods that can search through large transactional datasets efficiently. A straightforward exhaustive search is theoretically possible but becomes computationally explosive as the number of items grows. Practical association rule mining therefore relies on specialized algorithms designed to avoid this combinatorial blow-up.

- **Brute force:**

- Enumerate all itemsets and all possible rules
- Compute support and confidence for each
- Grows exponentially; infeasible for real datasets

- **Efficient algorithms:**

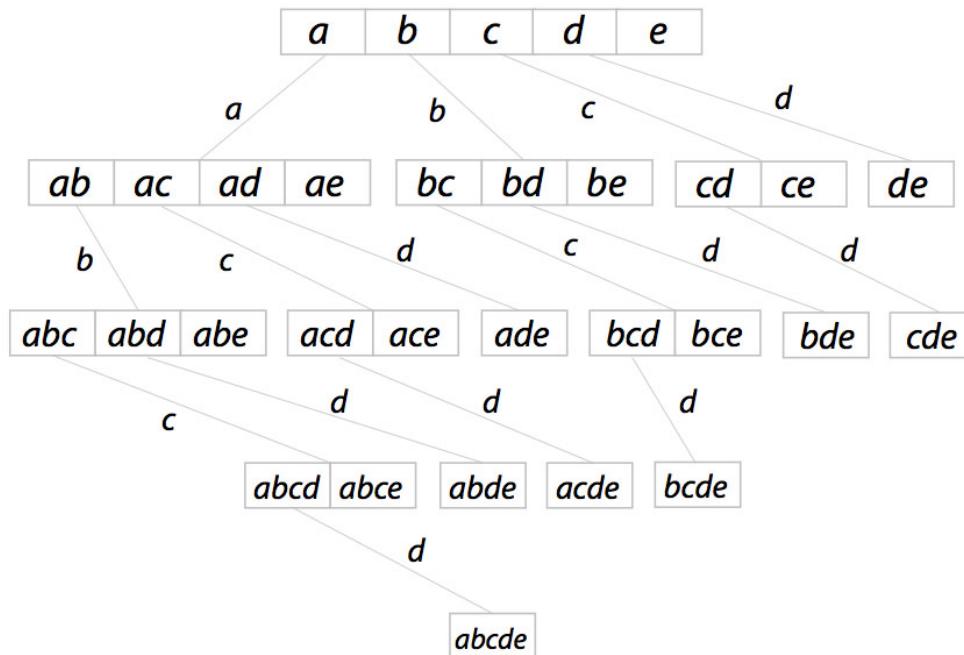

- **Apriori** – level-wise search with pruning
- **FP-Growth** – compresses data into FP-tree, avoids candidate generation
- **Eclat** – uses vertical data format and intersections
- All reduce the search space dramatically compared to brute force

The Apriori Algorithm

Apriori is a classic algorithm for **finding frequent itemsets** and **deriving association rules** in transactional databases (e.g., shopping baskets, web logs). It is based on the idea that **every subset of a frequent itemset must also be frequent**.

Key points:

- Proposed by **Agrawal & Srikant (1994)**.
- Works on **transaction data** (e.g., sets of items bought together).
- First finds **frequent single items**, then **grows** them into larger itemsets as long as they remain frequent.
- Uses a **bottom-up, level-wise** search with **candidate generation** and testing.
- Stops when **no more frequent extensions** can be found.
- The resulting frequent itemsets are used to build **association rules** (e.g., for **market basket analysis**).

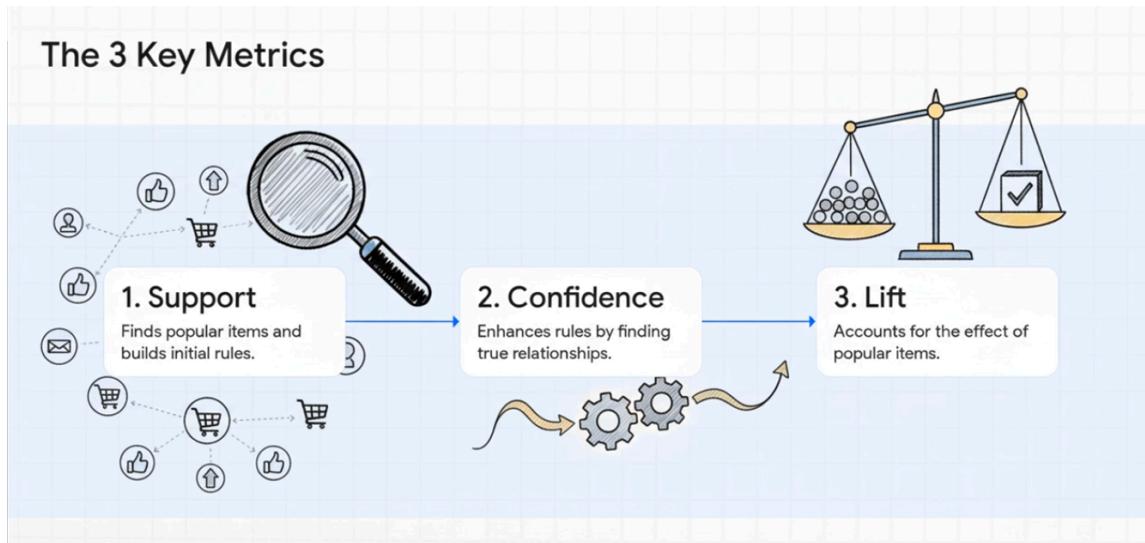

- This diagram shows the candidate itemset generation structure used by the Apriori algorithm.
- Each level represents itemsets of increasing size, starting from single items at the top and building toward larger combinations below.
- Apriori works by repeatedly joining frequent itemsets to form larger candidates, while pruning any itemset whose subsets were not frequent in earlier steps.
- In the diagram, every node represents a candidate itemset, and the lines show how each larger set is generated from smaller ones by adding one item at a time.

- Only itemsets whose all subsets appear in the previous level are kept, which reduces the search space.
- In essence, the figure visualizes the core Apriori idea: grow itemsets level by level, but prune aggressively using the principle that all subsets of a frequent itemset must themselves be frequent.

Creating Association Rules using The Apriori Algorithm

To create association rules, we use 3 metrics:

1. Support: finds the popular items and builds initial rules.
2. Confidence: Enhance initial rules by finding true relationships.
3. Lift: Enhance rules by accomodating for popular items effect ($x \rightarrow y$ where x is popular e.g. bread in a bakery)

1. Support Measure

Support measures **how often** an itemset appears in the dataset.

It is a probability-like measure between 0 and 1.

Definition

$$\text{Support}(X) = \frac{\text{Number of transactions containing } X}{\text{Total transactions}}$$

Range

- $0 \leq \text{Support}(X) \leq 1$
 - $0 \rightarrow X$ never appears
 - $1 \rightarrow X$ appears in every transaction

Interpretation

- **High support** → X is common, good candidate for rules
- **Low support** → X is rare, often less useful (unless domain-specific)

Thresholds in practice

- Set a **minimum support** to filter out infrequent itemsets.
- Typical starting points:
 - **5–10%** for large retail datasets
 - **20–30%** for smaller datasets or only very popular combinations
- Too high → you miss interesting but less frequent patterns
- Too low → you keep many unimportant, noisy patterns

Example

Let's assume that we have a small dataset with 12 transactions:

Transaction ID	Item 1	Item 2	Item 3	Item 4	Item 5
1	Milk	Egg	Bread	Butter	
2	Milk	Butter	Egg	Ketchup	
3	Bread	Butter	Ketchup		
4	Milk	Bread	Butter		
5	Bread	Butter	Cookies		
6	Milk	Bread	Butter	Cookies	
7	Milk	Cookies			
8	Milk	Bread	Butter		
9	Bread	Butter	Egg	Cookies	
10	Milk	Butter	Bread		
11	Milk	Bread	Butter		
12	Milk	Bread	Cookies	Ketchup	

First, we set out the **Minimum Support** value to:

- 50% (focus on items present in at least half of the transactions), this value can be set to 5% or 10% in real-life situations with large datasets.

Step 1: Dataset Transformation Convert the dataset into a binary format:

Transaction	Milk	Egg	Bread	Butter	Ketchup	Cookies
1	1	1	1	1	0	0

Transaction	Milk	Egg	Bread	Butter	Ketchup	Cookies
2	1	1	0	1	1	0
3	0	0	1	1	1	0
4	1	0	1	1	0	0
5	0	0	1	1	0	1
6	1	0	1	1	0	1
7	1	0	0	0	0	1
8	1	0	1	1	0	0
9	0	1	1	1	0	1
10	1	0	1	1	0	0
11	1	0	1	1	0	0
12	1	0	1	0	1	1

Step 2: Identify Frequent 1-Itemsets

The algorithm starts by calculating the support for each single item.

Item	Support Count	Support (%)	Frequent?
Milk	9	75%	Yes
Egg	3	25%	No
Bread	10	83%	Yes
Butter	10	83%	Yes
Ketchup	3	25%	No
Cookies	5	42%	No

Frequent 1-itemsets: {Milk} , {Bread} , {Butter} .

Step 3: Generate 2-Itemsets

Now, combine frequent 1-itemsets into 2-itemsets and calculate their support.

Itemset	Support Count	Support (%)	Frequent?
{Milk, Bread}	7	58%	Yes
{Milk, Butter}	7	58%	Yes
{Bread, Butter}	9	75%	Yes

Frequent 2-itemsets: {Milk, Bread} , {Milk, Butter} , {Bread, Butter} .

Step 4: Generate 3-Itemsets

Combine frequent 2-itemsets into 3-itemsets and calculate their support.

Itemset	Support Count	Support (%)	Frequent?
{Milk, Bread, Butter}	6	50%	Yes

Frequent 3-itemset: {Milk, Bread, Butter} .

Step 5: No Larger Itemsets Can Be Created

Since there are no frequent 4-itemsets (support would drop below 50%), we stop here.

Step 6: Generate Initial Association Rules

Now, use the frequent itemsets to generate association rules, we will focus on the largest item set, we can create rules from smaller ones if needed.

Rules from {Milk, Bread, Butter} :

1. Rule 1:

Milk, Bread → Butter

$$\text{Support} = P(\text{Milk, Bread, Butter}) = 6/12 = 50\%$$

1. Rule 2:

Milk, Butter → Bread

$$\text{Support} = P(\text{Milk, Bread, Butter}) = 6/12 = 50\%$$

2. Rule 3:

Bread, Butter → Milk

$$\text{Support} = P(\text{Milk, Bread, Butter}) = 6/12 = 50\%$$

Why Support Is Not Enough (SmartBuy Example)

Support is **symmetric**, it does not give us the direction of the relation, it tells us **how often they appear together**, but not **which direction** is more useful.

For example, assume SmartBuy has **1,000 transactions** in a certain period, and we observe:

- 200 transactions include a **Phone**
- 800 transactions include a **Cover**
- 120 transactions include **both** a Phone and a Cover

So the **support** of the pair is:

$$\text{support}(\text{Phone} \cap \text{Cover}) = \frac{120}{1000} = 12$$

This 12% is the same for both:

- Phone → Cover
- Cover → Phone

Support alone just says: "*Phones and covers occur together in 12% of all SmartBuy transactions.*" It does **not** tell us which rule is actually useful.

Direction 1: Phone → Cover (Makes Sense)

$$\text{confidence}(\text{Phone} \rightarrow \text{Cover}) = \frac{\text{support}(\text{Phone} \cap \text{Cover})}{\text{support}(\text{Phone})} = \frac{120/1000}{200/1000} = \frac{120}{200} = 60$$

Interpretation:

In **60%** of transactions where a customer buys a **phone**, they also buy a **cover**.

This is a **strong rule** and very reasonable: If someone is buying a phone, suggesting a cover is a good cross-sell.

Direction 2: Cover → Phone (Much Weaker)

$$\text{confidence}(\text{Cover} \rightarrow \text{Phone}) = \frac{\text{support}(\text{Phone} \cap \text{Cover})}{\text{support}(\text{Cover})} = \frac{120/1000}{800/1000} = \frac{120}{800} = 15$$

Interpretation:

In only **15%** of transactions where a customer buys a **cover**, they also buy a **phone**.

This is **quite low**. Most people buying covers already **have** a phone, so suggesting a new phone when they buy a cover is usually **not useful**.

Takeaway

- Same support for the pair: $\text{support}(\text{Phone} \cap \text{Cover}) = 12$
- Very different confidences:
 - Phone → Cover: **60%** (strong, useful rule)
 - Cover → Phone: **15%** (weak, not very useful)

So even though **support is the same**, only

Phone → Cover

really makes sense as a business rule; the reverse direction does not.

2. Confidence Measure

To choose the more useful rule, we use **confidence**.

Definition

Confidence measures how often (Y) appears when (X) appears (how reliable the rule is):

$$\text{conf}(X \rightarrow Y) = \frac{\text{support}(X \cap Y)}{\text{support}(X)}.$$

- **Range:** $(0 \leq \text{conf}(X \rightarrow Y) \leq 1)$
 - $0 \rightarrow$ the rule never holds
 - $1 \rightarrow$ the rule always holds

Interpretation

- **High confidence (~1):** when (X) happens, (Y) almost always happens (strong rule).
- **Low confidence (~0):** when (X) happens, (Y) rarely happens (weak rule).

In practice, we often set a **minimum confidence threshold** (e.g., 70–80%) and keep only rules above that value.

.....

Step 7: Validate the Rules using Confidence

First, let us set the **Minimum Confidence** value to: 70%.

Rules from {Milk, Bread, Butter} :

1. Rule 1:

Milk, Bread \rightarrow Butter

$$\text{Confidence} = P(\text{Butter}|\text{Milk, Bread}) = \frac{P(\text{Milk, Bread, Butter})}{P(\text{Milk, Bread})} = \frac{6}{7} = 85\%$$

1. Rule 2:

Milk, Butter \rightarrow Bread

$$\text{Confidence} = P(\text{Bread}|\text{Milk, Butter}) = \frac{P(\text{Milk, Bread, Butter})}{P(\text{Milk, Butter})} = \frac{6}{7} = 85\%$$

1. Rule 3:

Bread, Butter \rightarrow Milk

$$\text{Confidence} = P(\text{Milk} | \text{Bread, Butter}) = \frac{P(\text{Milk, Bread, Butter})}{P(\text{Bread, Butter})} = \frac{6}{9} \approx 66\%$$

3. Lift Measure

Confidence alone can be **misleading** when the consequent (Y) is very frequent: a rule ($X \rightarrow Y$) may have high confidence just because (Y) is common.

Example (bakery)

- $P(\text{bread}) = 0.80$
- $P(\text{cake}) = 0.20$
- $P(\text{cake} \cap \text{bread}) = 0.16$

Then:

$$\text{conf}(\text{cake} \rightarrow \text{bread}) = \frac{0.16}{0.20} = 0.8$$

Confidence is 80%, but bread is already in 80% of all orders, so cake buyers are **not** more likely than average to buy bread.

To correct for this, we use **lift**:

$$\text{Lift}(X \rightarrow Y) = \frac{\text{Confidence}(X \rightarrow Y)}{\text{Support}(Y)} = \frac{P(Y|X)}{P(Y)}$$

In the example:

$$\text{lift}(\text{cake} \rightarrow \text{bread}) = \frac{0.8}{0.8} = 1$$

.....

Interpreting Lift

Lift measures how strongly two items or itemsets are associated:

- ($\text{lift} > 1$): items occur together **more often than expected** (positive association).
- ($\text{lift} = 1$): items occur together **as often as expected** under independence (no association).
- ($\text{lift} < 1$): items occur together **less often than expected** (negative association).

So lift tells us whether items co-occur more (or less) frequently than expected under independence, making it a useful complement to confidence.

.....

Step 8: Validate Rules using the Lift

First, we set the **Lift > 1** for actionable rules

1. Rule 1:

Milk, Bread → Butter

$$\text{Lift} = \frac{P(\text{Butter}|\text{Milk, Bread})}{P(\text{Butter})} = \frac{0.85}{0.83} \approx 1.02$$

2. Rule 2:

Milk, Butter → Bread

$$\text{Lift} = \frac{P(\text{Bread}|\text{Milk, Butter})}{P(\text{Bread})} = \frac{0.85}{0.83} \approx 1.02$$

3. Rule 3:

Bread, Butter → Milk

$$\text{Lift} = \frac{P(\text{Milk}|\text{Bread, Butter})}{P(\text{Milk})} = \frac{0.66}{0.75} \approx .88$$

Final Results

Frequent Itemsets:

- **1-itemsets:** {Milk}, {Bread}, {Butter}
- **2-itemsets:** {Milk, Bread}, {Milk, Butter}, {Bread, Butter}
- **3-itemset:** {Milk, Bread, Butter}

Rules:

Rule	Support	Confidence	Lift	Actionable?
Milk, Bread → Butter	50%	85%	1.02	Yes
Milk, Butter → Bread	50%	85%	1.02	Yes
Bread, Butter → Milk	50%	66%	.88	No

Interpretation and Actionable Insights

Rule	Explanation
Milk, Bread → Butter	Customers buying Milk and Bread are highly likely (85%) to also buy Butter. Consider bundling these items.
Milk, Butter → Bread	Strong association; placing these items together could increase sales.
Bread, Butter → Milk	Suggests that Milk is a complementary product to Bread and Butter, Weak lift thought

Python Example

We will implement the **Apriori algorithm** using the `mlxtend` library for frequent itemset mining and rule generation.

a. Install Required Libraries Make sure you have the required libraries installed:

```
pip install pandas mlxtend
```

b. Load the Dataset We will represent the dataset as a **binary transaction matrix** where each row is a transaction, and each column is an item (1 = purchased, 0 = not purchased).

```
In [1]: import pandas as pd

# Define the dataset
data = {
    "Milk": [1, 1, 0, 1, 0, 1, 1, 1, 0, 1, 1, 1],
    "Egg": [1, 1, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0],
    "Bread": [1, 0, 1, 1, 1, 1, 0, 1, 1, 1, 1, 1],
    "Butter": [1, 1, 1, 1, 1, 1, 0, 1, 1, 1, 1, 0],
    "Ketchup": [0, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 1],
    "Cookies": [0, 0, 0, 0, 1, 1, 1, 0, 1, 0, 0, 1],
}

# Create a DataFrame
df = pd.DataFrame(data)
print("Transaction Dataset:")
df
```

Transaction Dataset:

Out[1]:

	Milk	Egg	Bread	Butter	Ketchup	Cookies
0	1	1	1	1	0	0
1	1	1	0	1	1	0
2	0	0	1	1	1	0
3	1	0	1	1	0	0
4	0	0	1	1	0	1
5	1	0	1	1	0	1
6	1	0	0	0	0	1
7	1	0	1	1	0	0
8	0	1	1	1	0	1
9	1	0	1	1	0	0
10	1	0	1	1	0	0
11	1	0	1	0	1	1

c. Apply the Apriori Algorithm We will use the `mlxtend` library to find frequent itemsets and generate association rules.

Generate rules based on confidence

```
In [ ]: # Step 2: Generate association rules based on confidence
rules = association_rules(frequent_itemsets, num_itemsets=len(df), metric="confidence")

# Display the rules
print("\nAssociation Rules:")
print(rules[['antecedents', 'consequents', 'support', 'confidence', 'lift']])
```

Association Rules:

	antecedents	consequents	support	confidence	lift
0	(Bread)	(Milk)	0.583333	0.700000	0.933333
1	(Milk)	(Bread)	0.583333	0.777778	0.933333
2	(Butter)	(Milk)	0.583333	0.700000	0.933333
3	(Milk)	(Butter)	0.583333	0.777778	0.933333
4	(Butter)	(Bread)	0.750000	0.900000	1.080000
5	(Bread)	(Butter)	0.750000	0.900000	1.080000
6	(Milk, Bread)	(Butter)	0.500000	0.857143	1.028571
7	(Butter, Milk)	(Bread)	0.500000	0.857143	1.028571

We can also generate rules based on lift

```
In [ ]: # Step 2: Generate association rules based on lift
rules = association_rules(frequent_itemsets, num_itemsets=len(df), metric="lift", min_threshold=0.6)

# Display the rules
print("\nAssociation Rules:")
print(rules[['antecedents', 'consequents', 'support', 'confidence', 'lift']])
```

Association Rules:

	antecedents	consequents	support	confidence	lift
0	(Butter)	(Bread)	0.75	0.900000	1.080000
1	(Bread)	(Butter)	0.75	0.900000	1.080000
2	(Milk, Bread)	(Butter)	0.50	0.857143	1.028571
3	(Butter, Milk)	(Bread)	0.50	0.857143	1.028571
4	(Bread)	(Butter, Milk)	0.50	0.600000	1.028571
5	(Butter)	(Milk, Bread)	0.50	0.600000	1.028571

e. Filter and Interpret Rules You can filter rules for high lift or specific itemsets.

```
In [ ]: # Filter rules with Lift > 1
filtered_rules = rules[rules['lift'] > 1]
print("\nFiltered Rules with Lift > 1:")
print(filtered_rules[['antecedents', 'consequents', 'support', 'confidence', 'lift']])
```

Filtered Rules with Lift > 1:

	antecedents	consequents	support	confidence	lift
0	(Butter)	(Bread)	0.75	0.900000	1.080000
1	(Bread)	(Butter)	0.75	0.900000	1.080000
2	(Milk, Bread)	(Butter)	0.50	0.857143	1.028571
3	(Butter, Milk)	(Bread)	0.50	0.857143	1.028571
4	(Bread)	(Butter, Milk)	0.50	0.600000	1.028571
5	(Butter)	(Milk, Bread)	0.50	0.600000	1.028571

Interpretation

1. Milk, Bread → Butter
 - Support = 58%, Confidence = 87.5%, Lift = 1.05.
 - Suggest bundling these items for promotions.
2. Milk, Butter → Bread
 - Similar metrics as above, showing strong relationships.
3. Bread, Butter → Milk
 - High confidence but slightly weaker lift, still actionable.

Two-Items Rules

If desired, we can focus on association rules where the antecedent (X) contains just **one item** (i.e., 1-item antecedent, 2 items in the rule overall).

Consider the rule:

Milk → Bread

Suppose we have **12 transactions**, and we observe:

- **Milk** appears in **9** transactions.
- **Milk and Bread together** appear in **7** transactions.

Then:

- **Support** of the rule is the fraction of all transactions that contain both Milk and Bread:
 $\text{supp}(\text{Milk} \rightarrow \text{Bread}) = \frac{7}{12} \approx 58\%$
- **Confidence** of the rule is the fraction of Milk-transactions that also contain Bread:
 $\text{conf}(\text{Milk} \rightarrow \text{Bread}) = \frac{7}{9} \approx 78\%$

So we can write the rule as:

Milk → Bread {S = 58%, C = 78%}.

2-Item Rules vs 3-Item Rules

2-Item Rules (e.g., Milk → Bread)

- **Simplicity:** Easy to read, explain, and act on.
- **Higher support and confidence (typically):** Fewer items need to co-occur, so these rules tend to appear more often in the data.
- **Broad applicability:** Capture general trends such as Milk → Bread, which can inform store layout (placing items nearby) or simple promotions.

3-Item Rules (e.g., Milk, Bread → Butter)

- **Deeper insights:** Reveal more specific patterns, like Milk, Bread → Butter that might not be visible in 2-item rules.
- **Lower support (usually):** All three items must appear together, so these combinations are naturally less frequent.
- **Targeted application:** Well-suited for niche marketing, personalized recommendations, or special bundle offers.

Which Is Better?

- Use **2-item rules** when you want:
 - General trends,
 - Simple explanations,
 - Broad business strategies (e.g., product placement, popular combos).
- Use **3-item rules** when you want:
 - More specific patterns,
 - Finer-grained understanding of customer behavior,
 - Targeted campaigns or tailored bundles.

There is no universally “better” rule size—the choice depends on your **data characteristics** (how dense/sparse the transactions are) and your **business objectives** (broad policies vs. targeted actions).
